This presentation gives an overview of our Structural Health Monitoring research with honeycomb panels

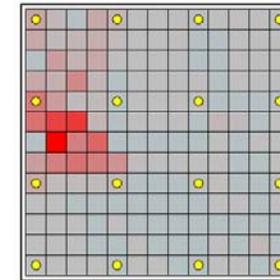

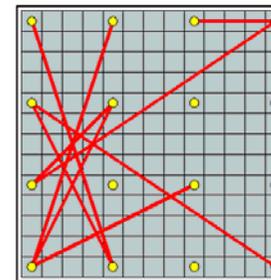

Background & Theory

Experimental Procedure

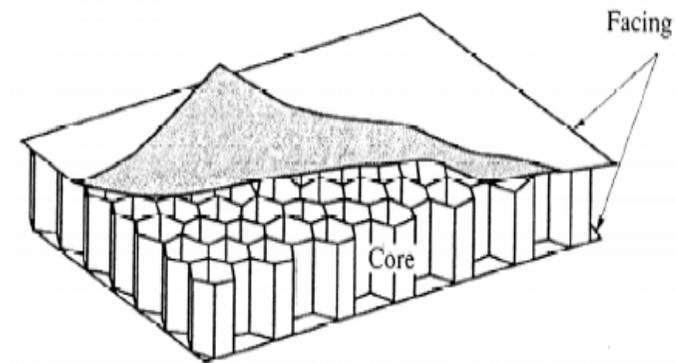

Results and Conclusions

Honeycomb panels offer a number of mechanical advantages useful in aerospace applications

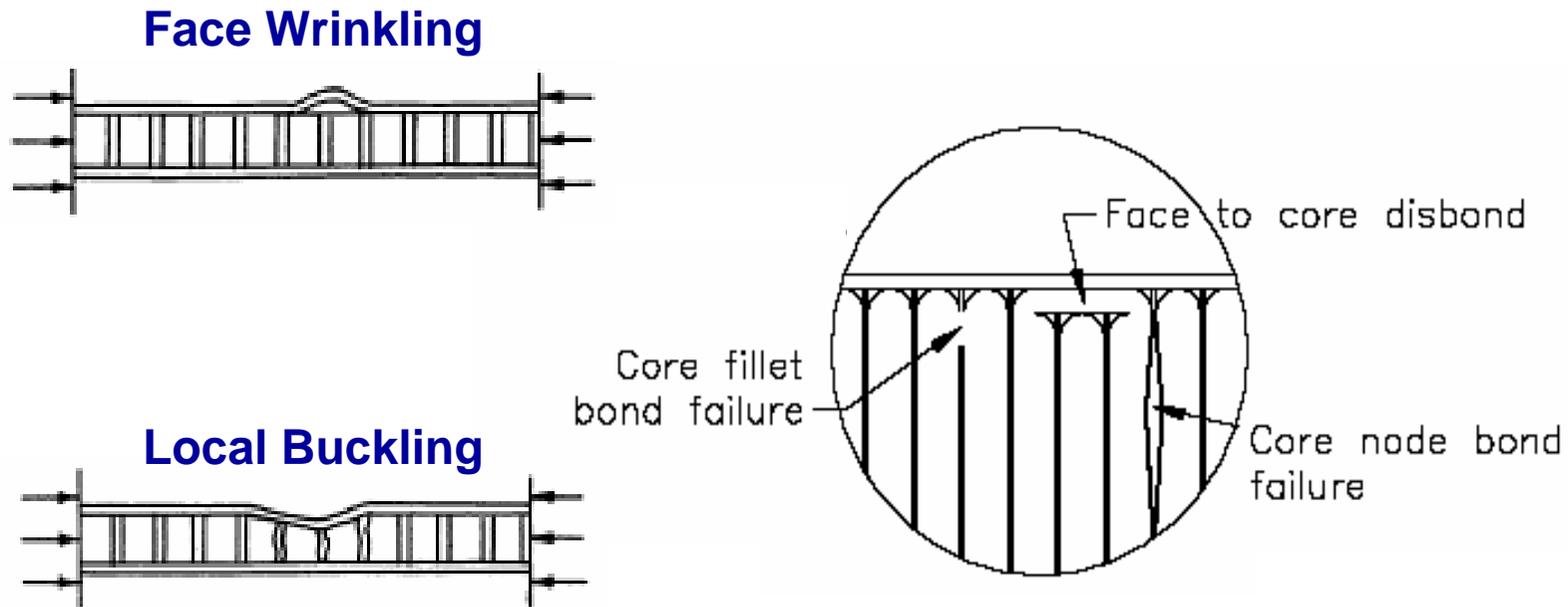

www.mae.usu.edu

Whitehead et. al 2000

Health monitoring of these panels reduces the likelihood of catastrophic structural failure.

Our goal was to detect and locate damage in a honeycomb aluminum panel

Whitehead et. al 2000

We used piezoelectric based active sensing to detect damage

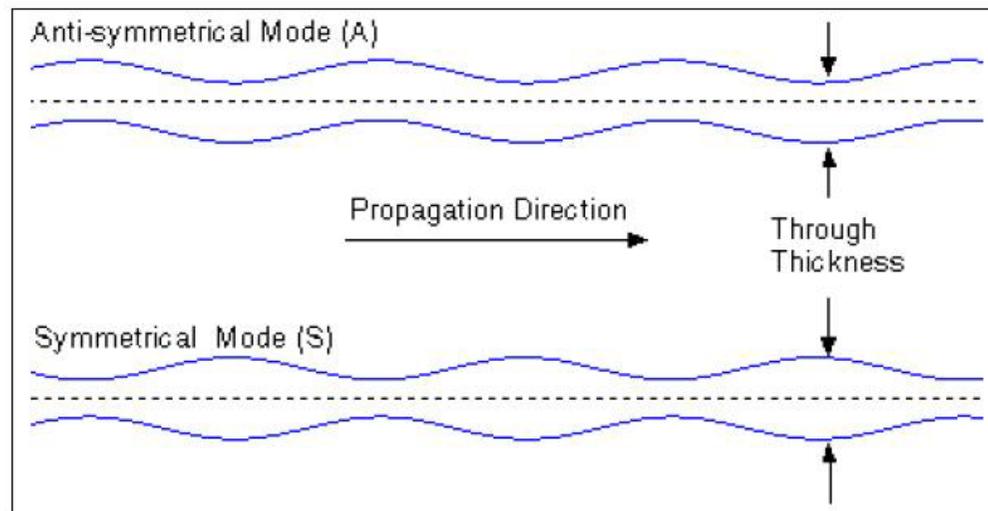

Our primary method of damage detection was through the use of Lamb wave propagation

Extractable Features

Attenuation

Reflection

Time of Arrival

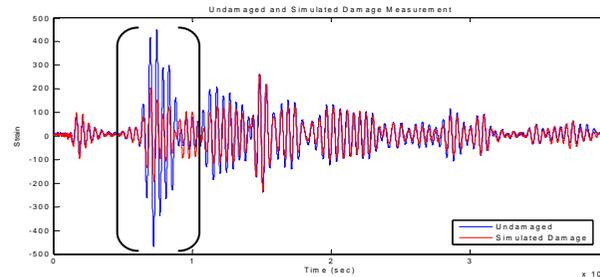

Kessler, et al. 2001

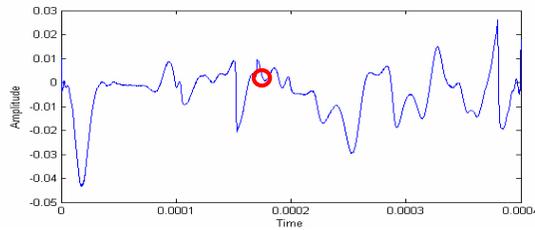

Lamb waves have wavelengths on the order of the thickness of the material

We employed four different methods for Lamb wave based damage detection

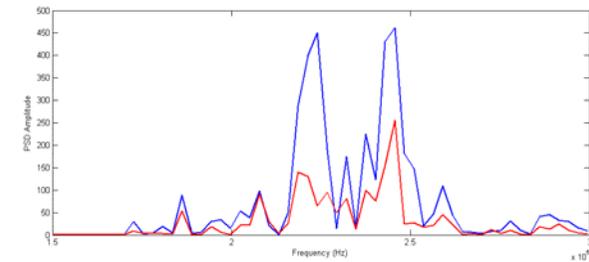

Wavelet Transform Integration

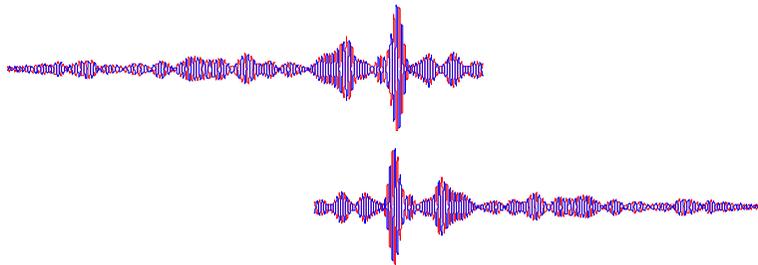

PSD Cross Correlation

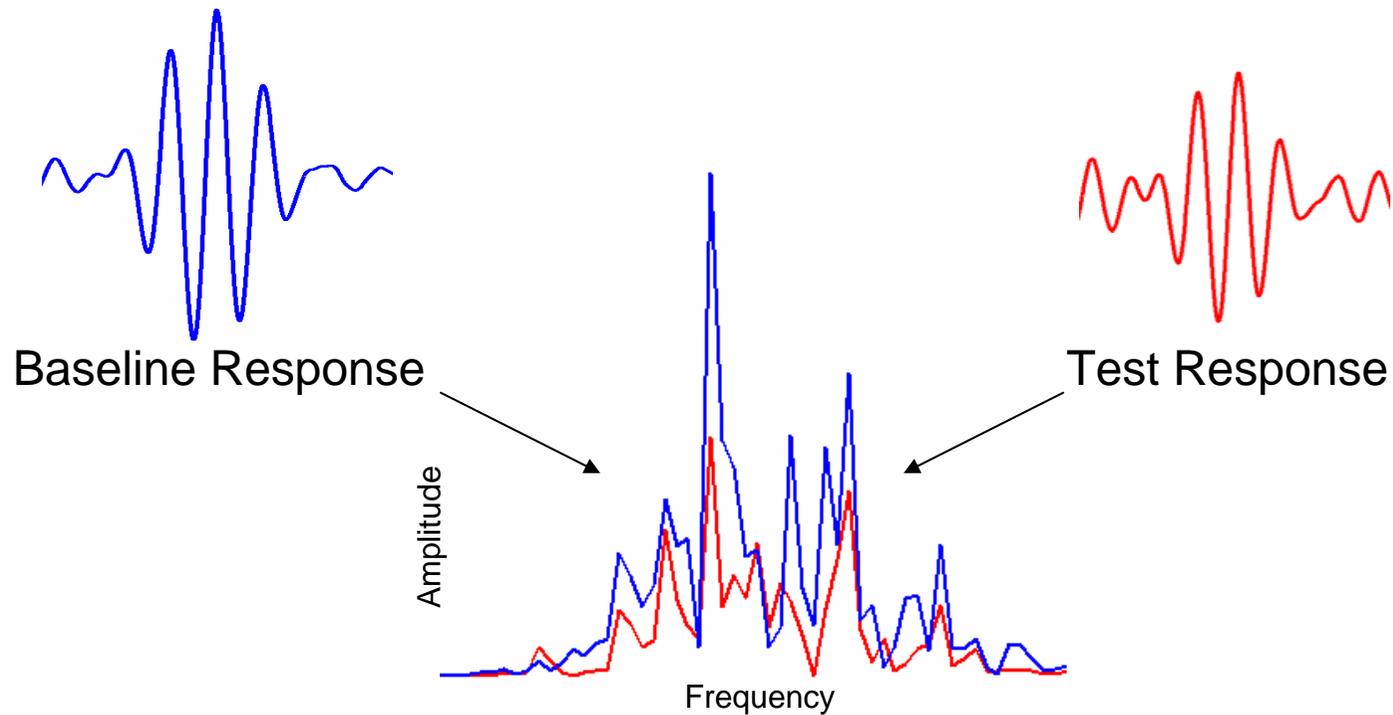

Wave Reflection Triangulation

Time Reversal

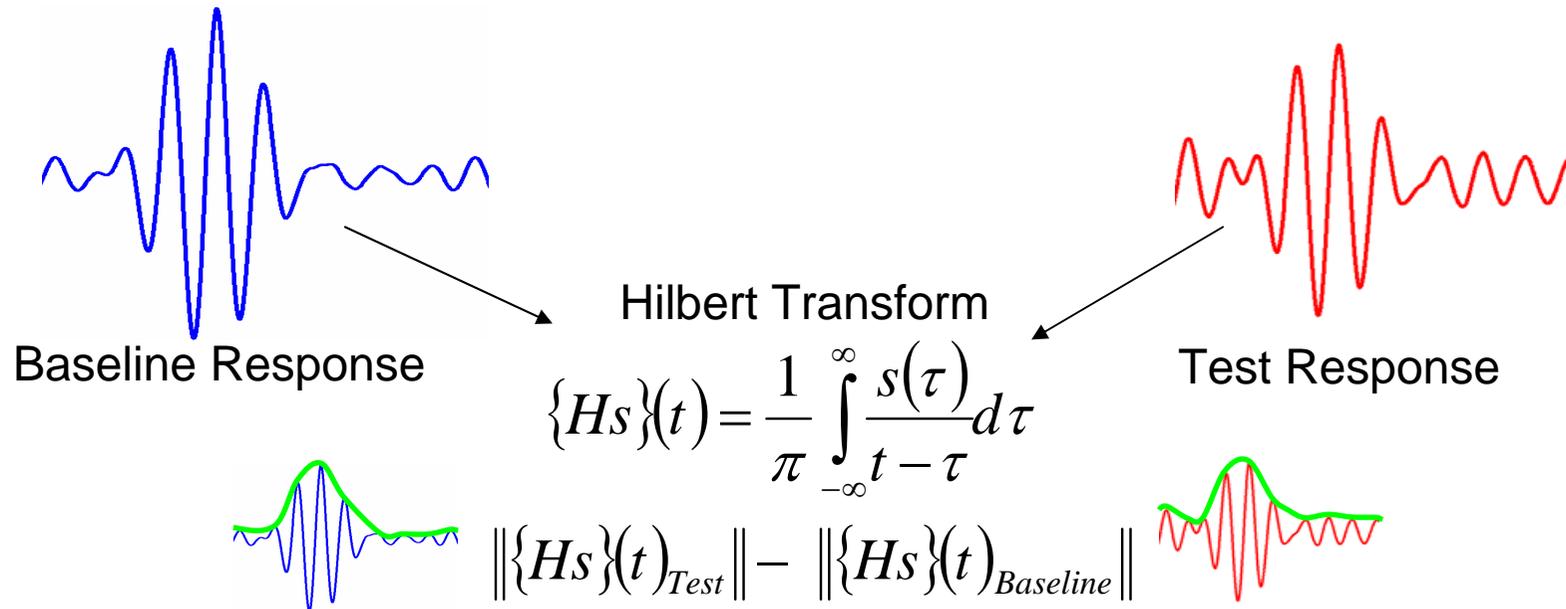

Power Spectral Density Cross Correlation

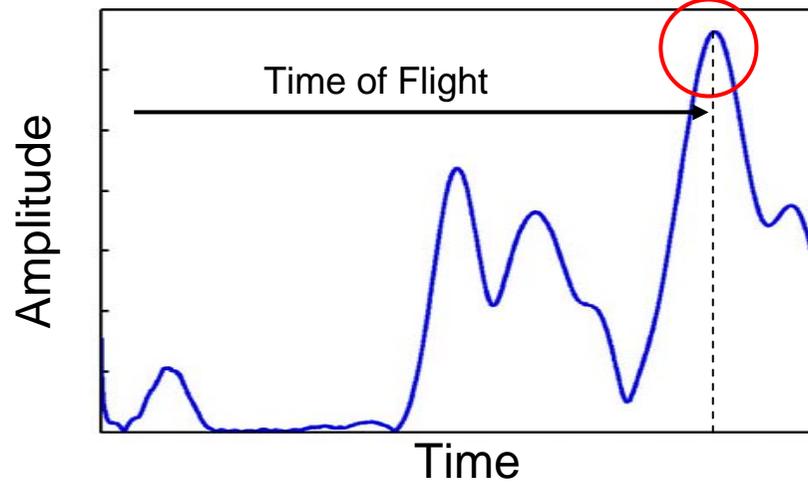

$$\text{DamageIndex} = r_{G_{yy_B} G_{yy_T}}$$

Maximum Cross Correlation \rightarrow r
 Baseline PSD \rightarrow G_{yy_B}
 Test PSD \rightarrow G_{yy_T}

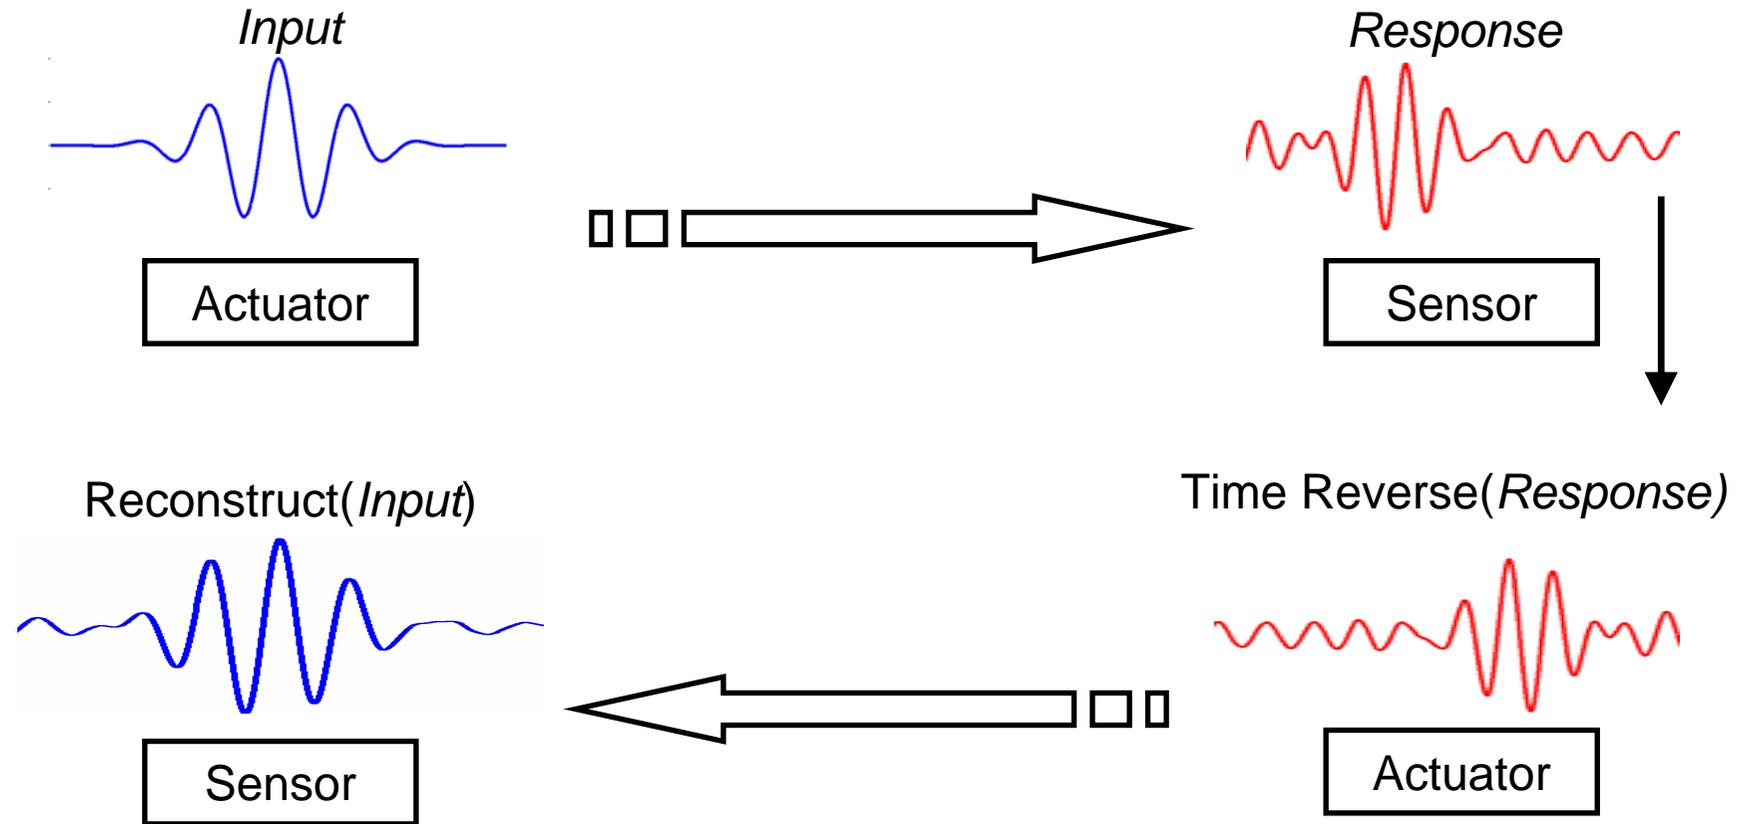

Wave Reflection Triangulation

Wait, et al. 2004

Time Reversal Acoustics

$$DamageIndex = \int (\text{Reconstruct}(Input) + \text{Reconstruct}(-Input)) dt$$

Health Of Plate Structures (H.O.P.S.) was developed to merge the various analysis methods

Data Acquisition Settings

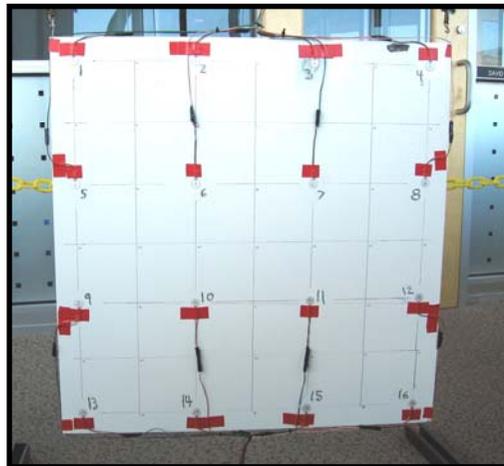

The screenshot displays the H.O.P.S. software interface. On the left is the 'Data Acquisition Settings' panel, which includes fields for 'Set DAQ Filename' (EricDanAndy\HOPSet\DAQ\Thick_722.d), 'Sampling Rate (MHz)' (25), 'Data Points \ Measurement' (10000), 'Pretigger Points' (100), 'Averages' (50), 'Actuator Voltage Range' (1), 'Sensor Voltage Range' (1), 'Actuator Signal Amplitude' (10), and 'Center Frequency' (250000). A 'Burst Type' dropdown menu is set to 'Morlet Wavelet'. Below these are 'Set DAQ Settings', 'Save Settings', 'Load Settings', and 'Copy Data' buttons.

The main interface is divided into four analysis panels:

- Wavelet:** Features two grid plots with yellow dots. Below the plots is a 'Threshold' field set to 1, and buttons for 'New DI', 'Wavelet', 'Baseline', 'Test', 'View DI', and 'View Set'.
- PSD:** Features two grid plots with yellow dots. Below the plots is a 'Threshold' field set to 1, and buttons for 'New DI', 'PSD', 'Baseline', 'Test', 'View DI', and 'View Set'.
- Triangulation:** Features a single grid plot with black dots. Below the plot is a 'Threshold' field set to 0.01, and buttons for 'Triangulation', 'View Set', 'Baseline', and 'Test'.
- Time Reversal:** Features a single grid plot with black dots. Below the plot is a 'Threshold' field set to 0.01, and buttons for 'T Reversal', 'View Set', 'Baseline', and 'Test'.

We instrumented two honeycomb panels of different thicknesses with arrays of PZT patches

61cm x 61cm x 6mm

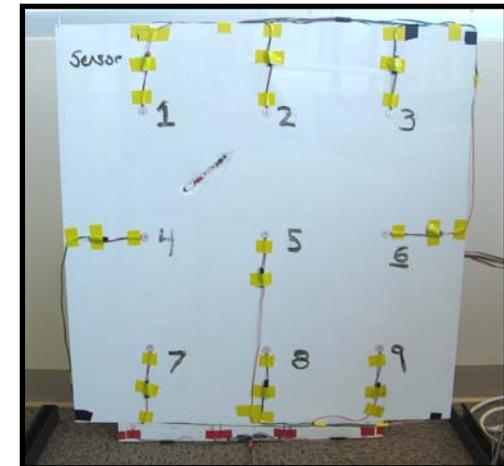

4 x 4 PZT Grid

Free-Free Support

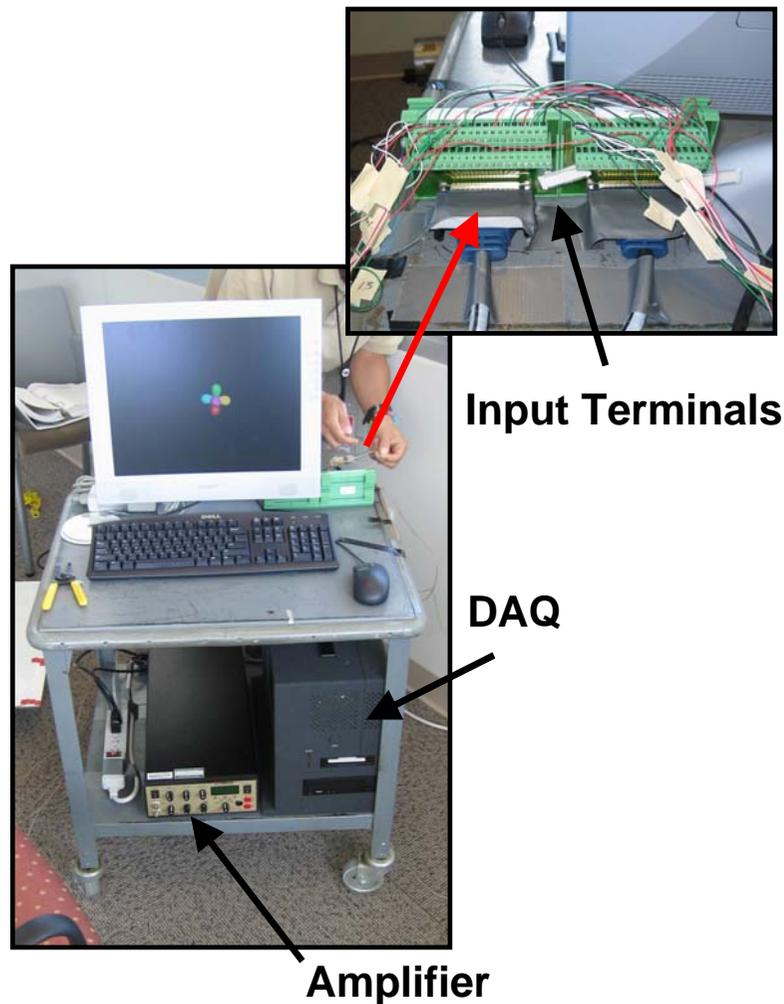

61cm x 61cm x 13mm

3 x 3 PZT Grid

Patches attached using standard super glue

Data were acquired using a commercially available data acquisition system

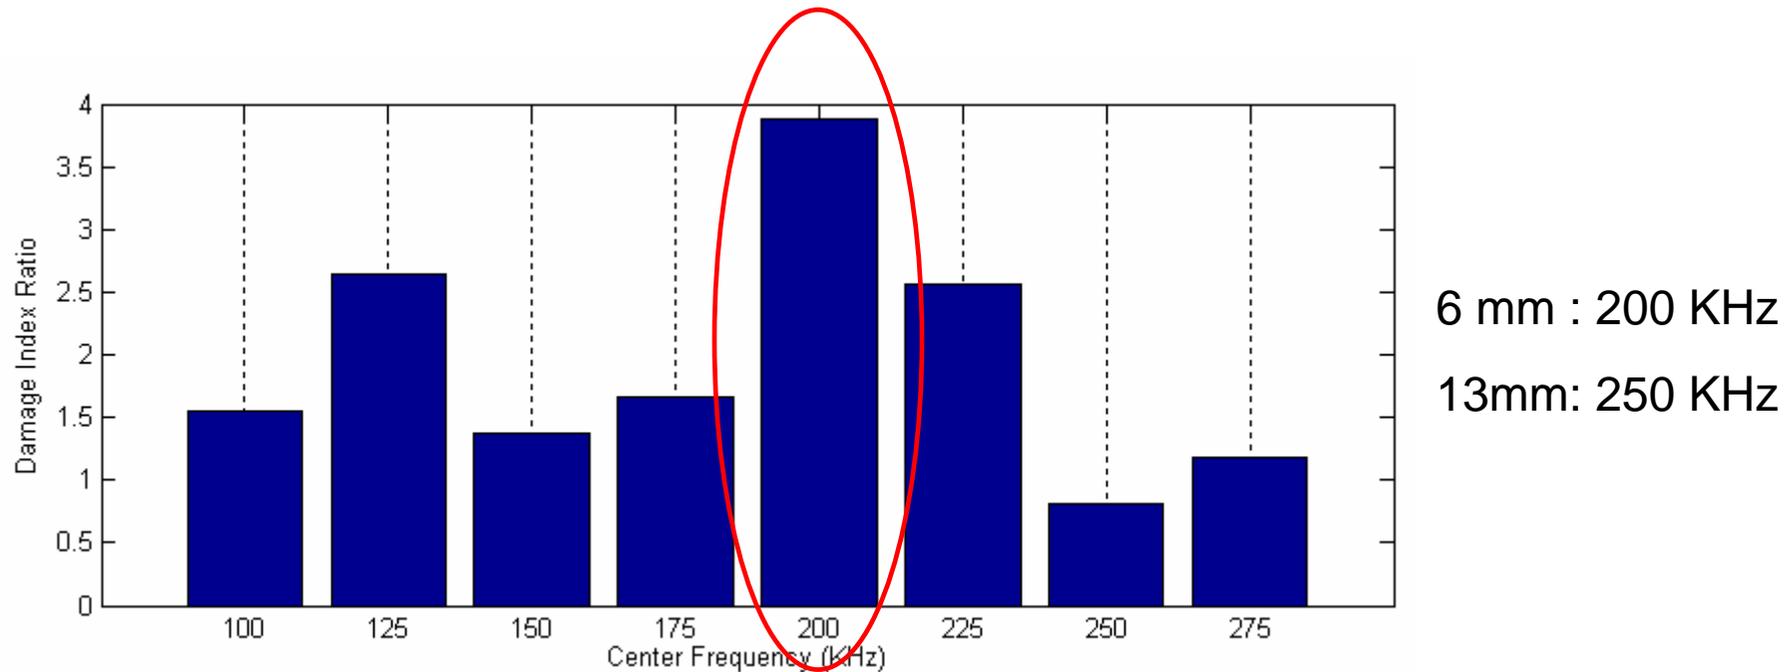

Each PZT was wired as both an actuator and sensor

Signals were multiplexed to one actuator and one sensor

Data acquired at a 25 MHz sampling rate

Due to model complexity, optimal Lamb wave center frequencies had to be determined experimentally

$$\text{Damage Index Ratio} = \frac{\text{Mean}(\text{Damage Indices of Damaged Paths})}{\text{Mean}(\text{Damage Indices of Undamaged Paths})}$$

Experimental Procedure

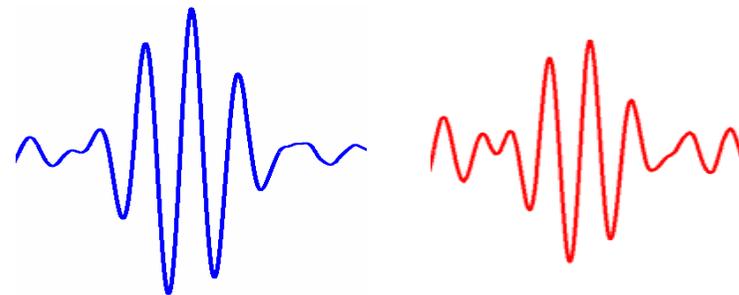

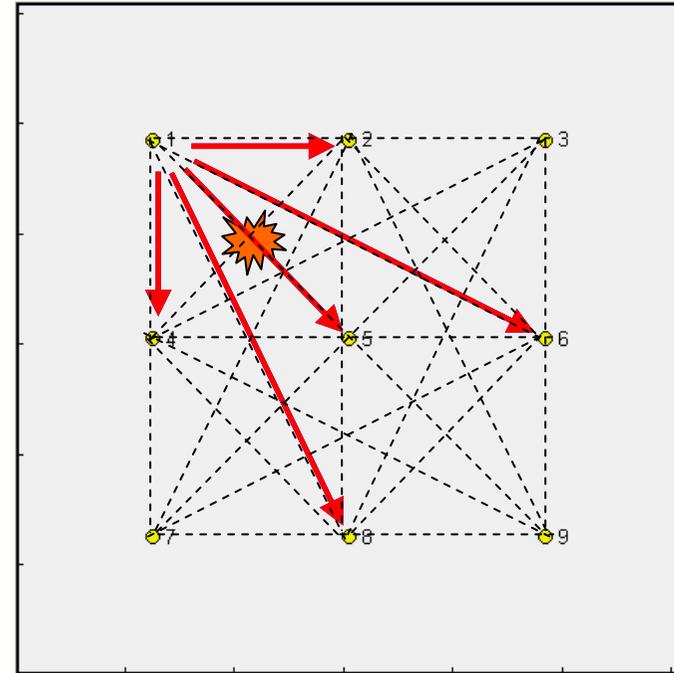

Assign actuator-sensor paths

Propagate Lamb wave from actuators to sensors to acquire baseline responses

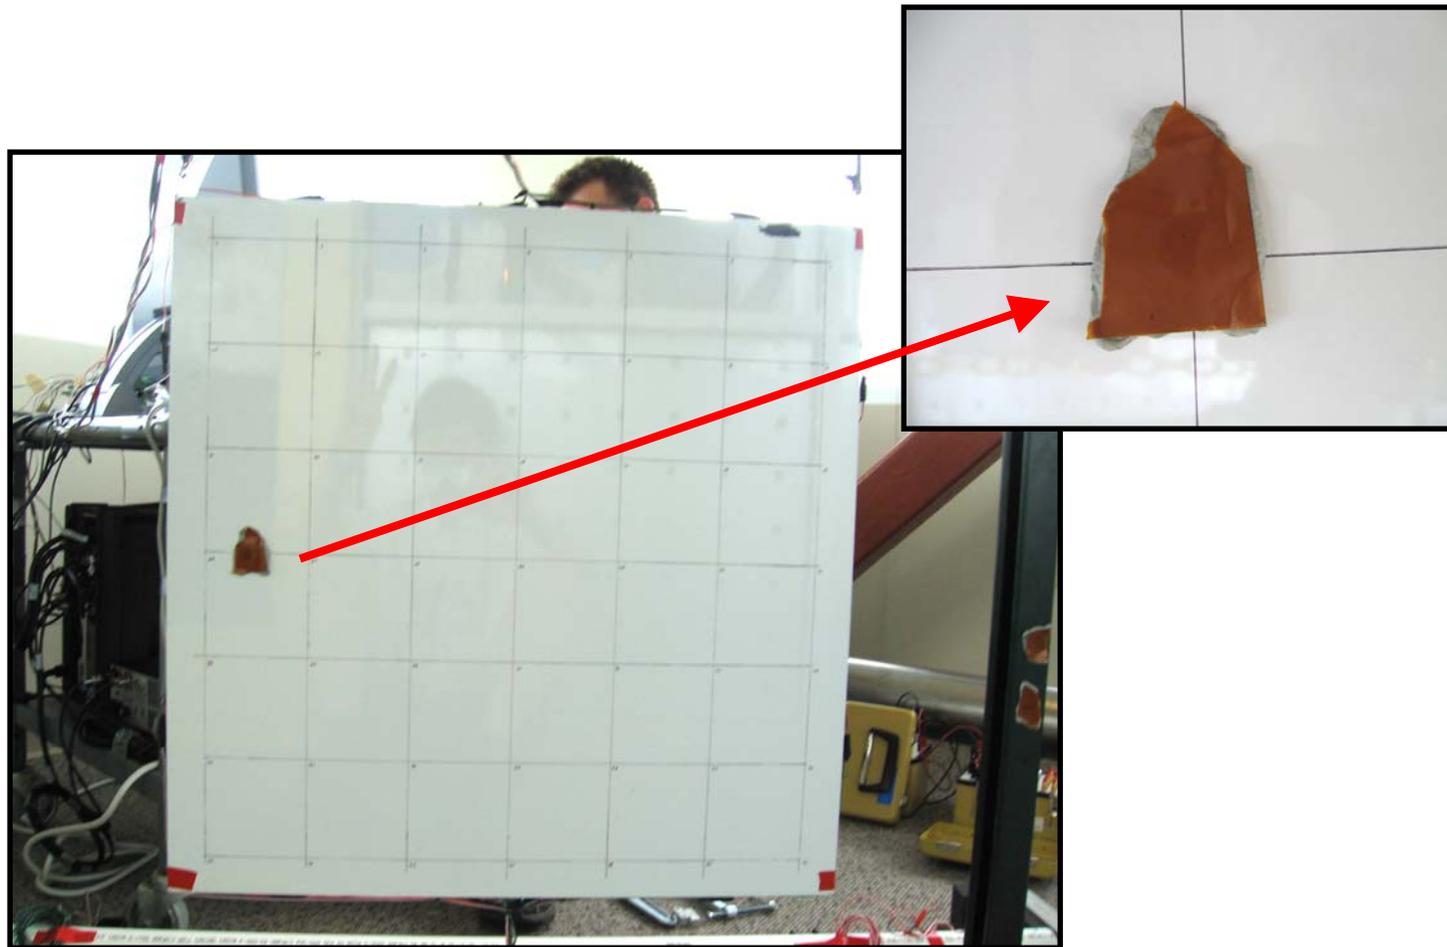

Apply damage (simulated or real)

Acquire test responses

Apply signal processing techniques

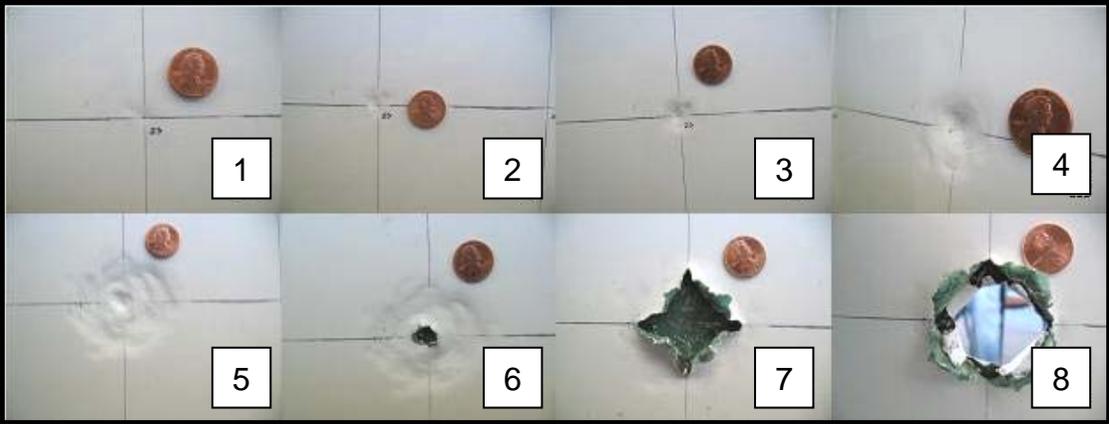

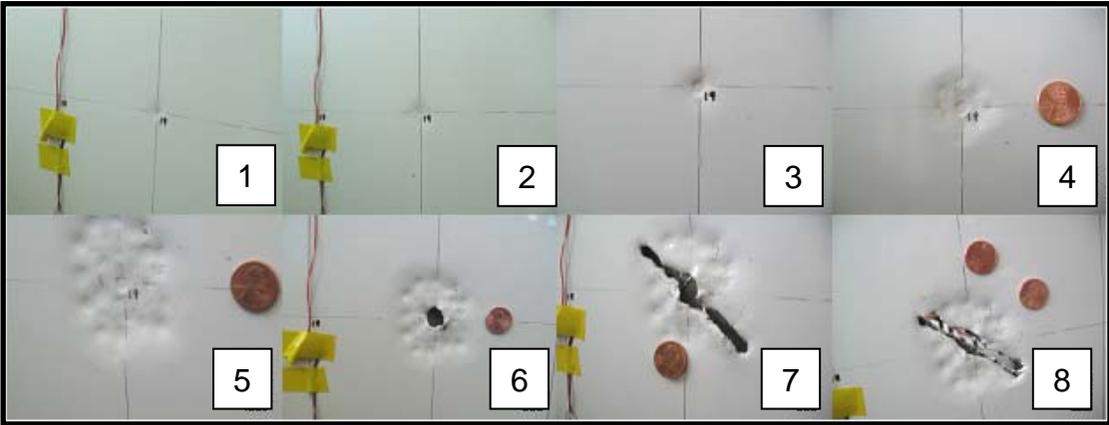

We first simulated damage by sticking industrial putty to honeycomb facing

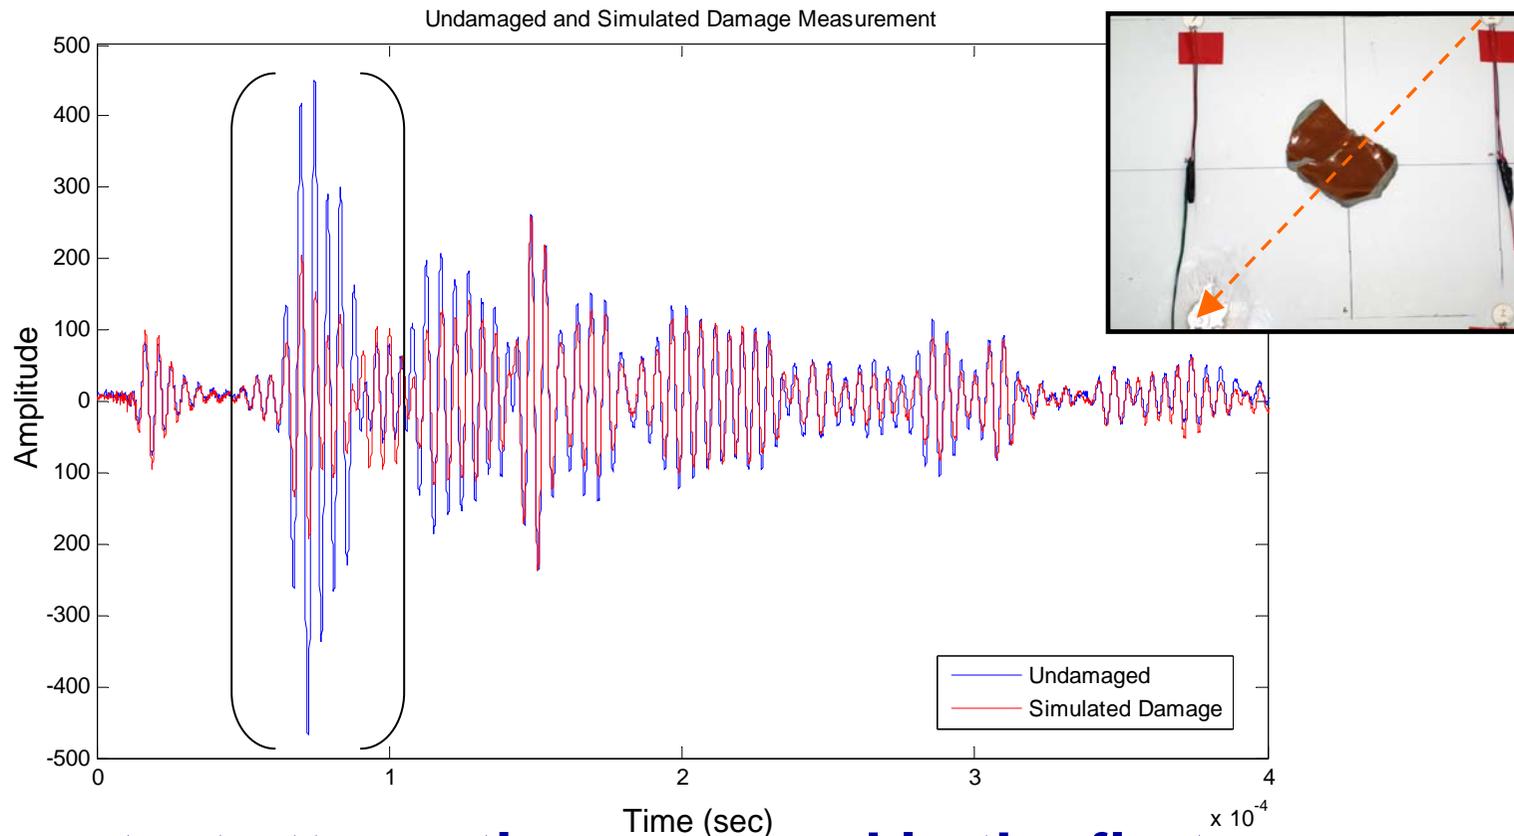

We then progressively added real damage by applying localized pressure to the *rear* facing

13 mm Plate

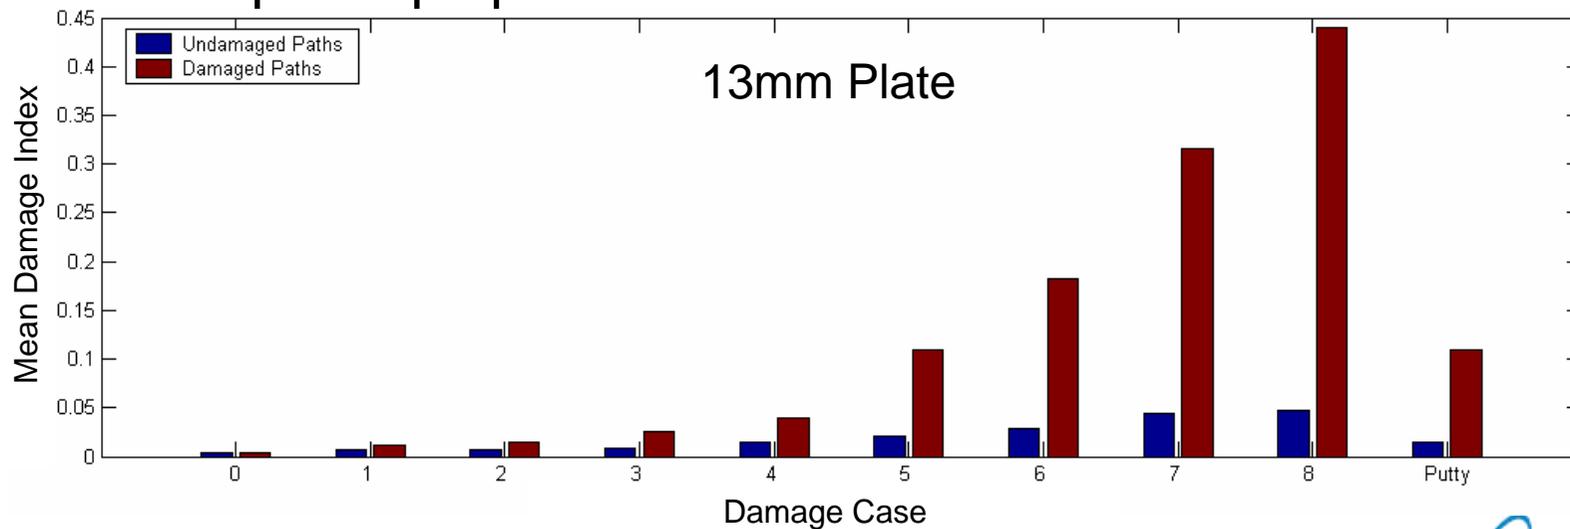

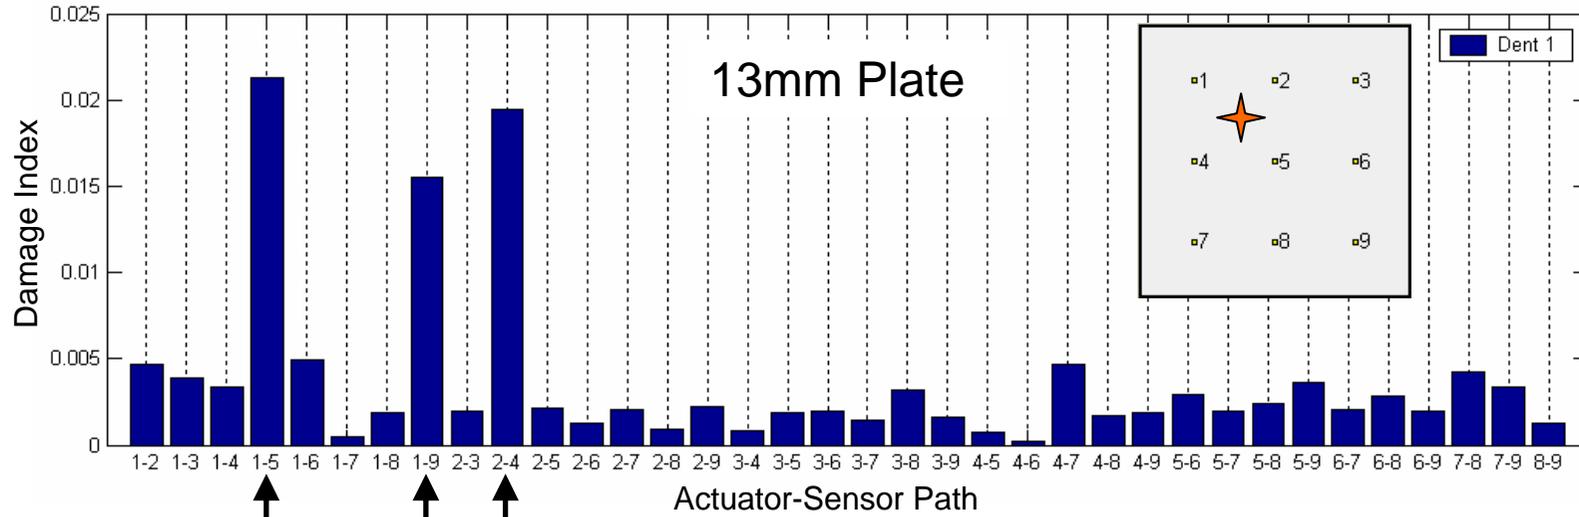

6 mm Plate

Visible levels of Lamb wave attenuation were observed as a result of adding simulated damage

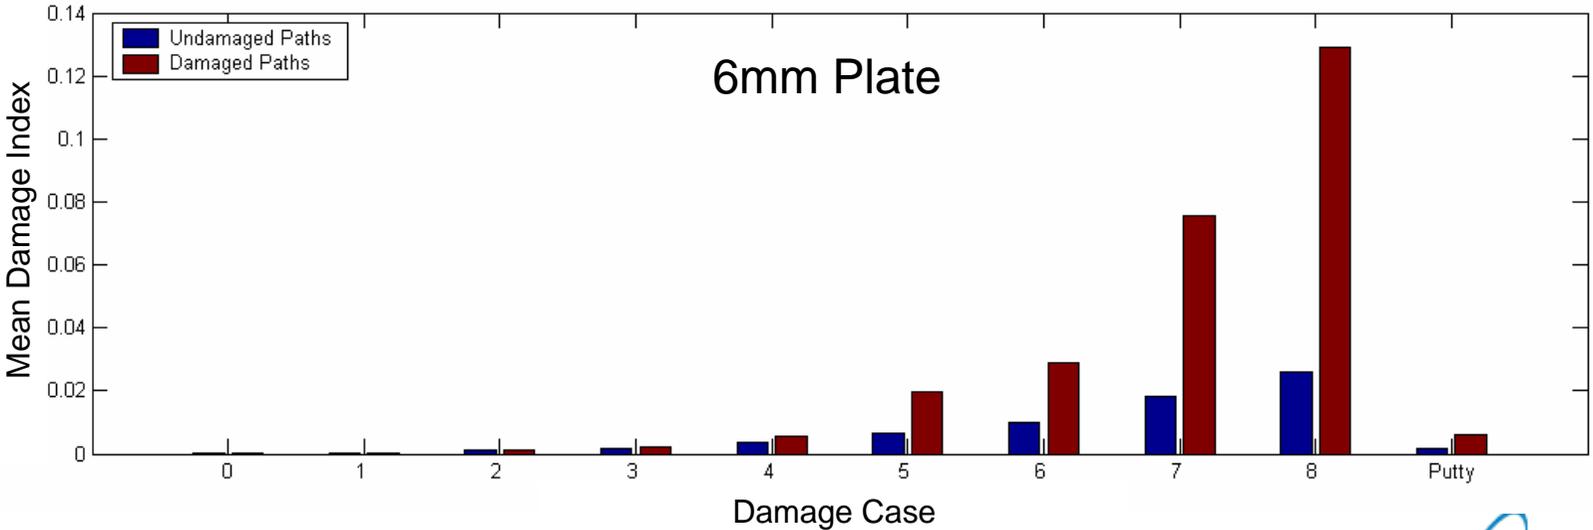

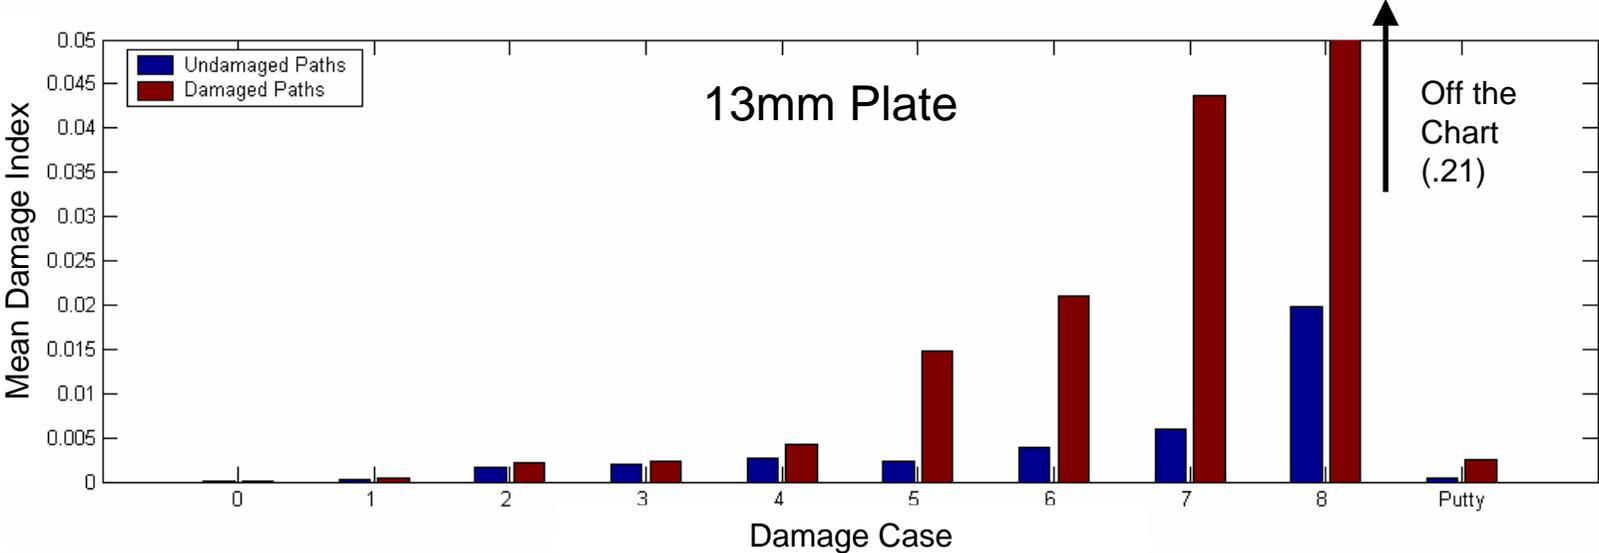

The greatest attenuation occurred in the first-arrival symmetric mode

Damage Index Results - Wavelet Transform

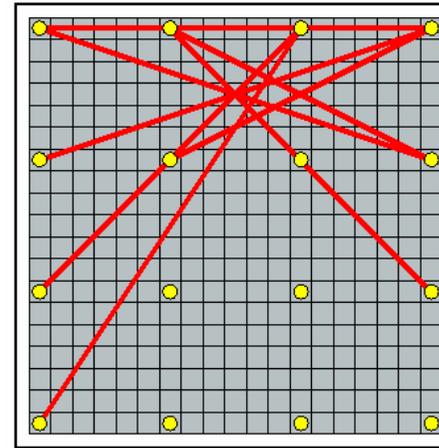

Damage Index Results – PSD Cross Correlation

After calculating a damage index for each path, we determined the damage location

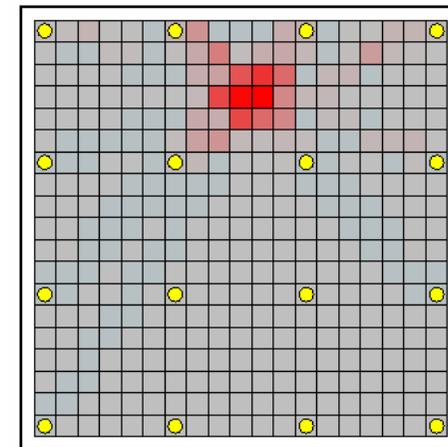

Find all paths > Damage Threshold

Form grid of boxes

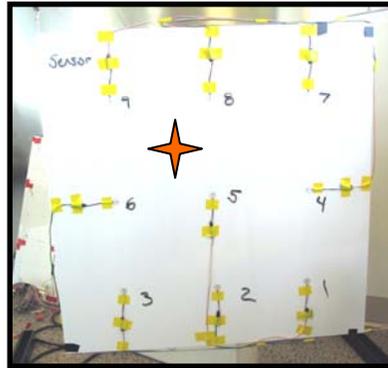

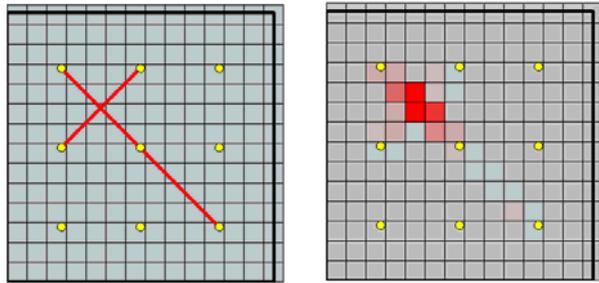

$$\text{Box damage} = \frac{\text{\# of damage crossings}}{\text{total \# of paths}}$$

Indicate box damage with red shading

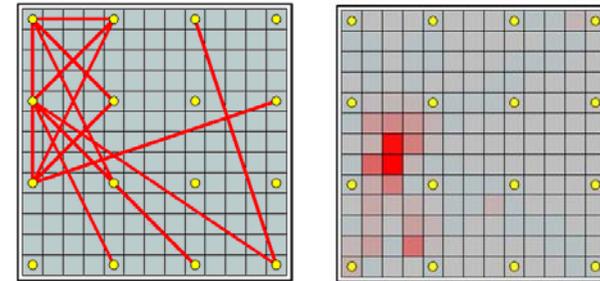

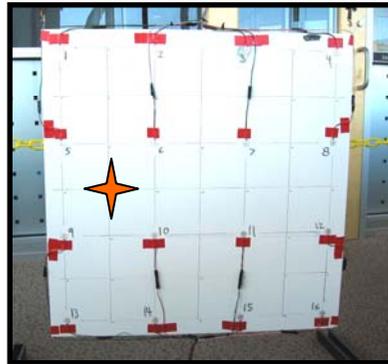

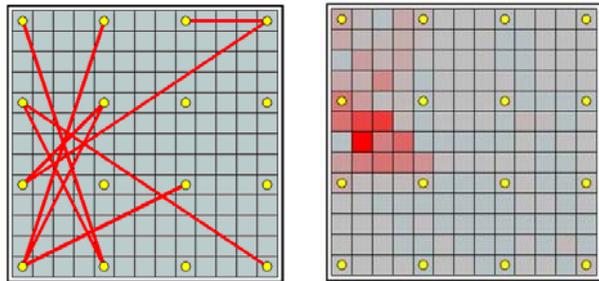

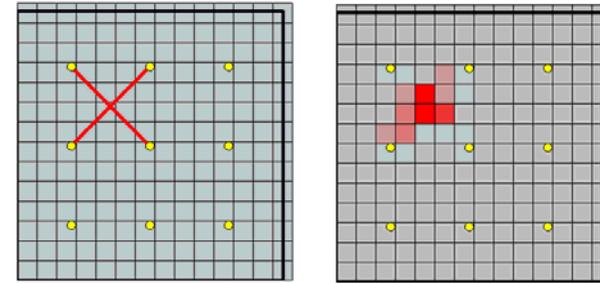

Damage Localization for Wavelet Transform and PSD Cross Correlation Methods

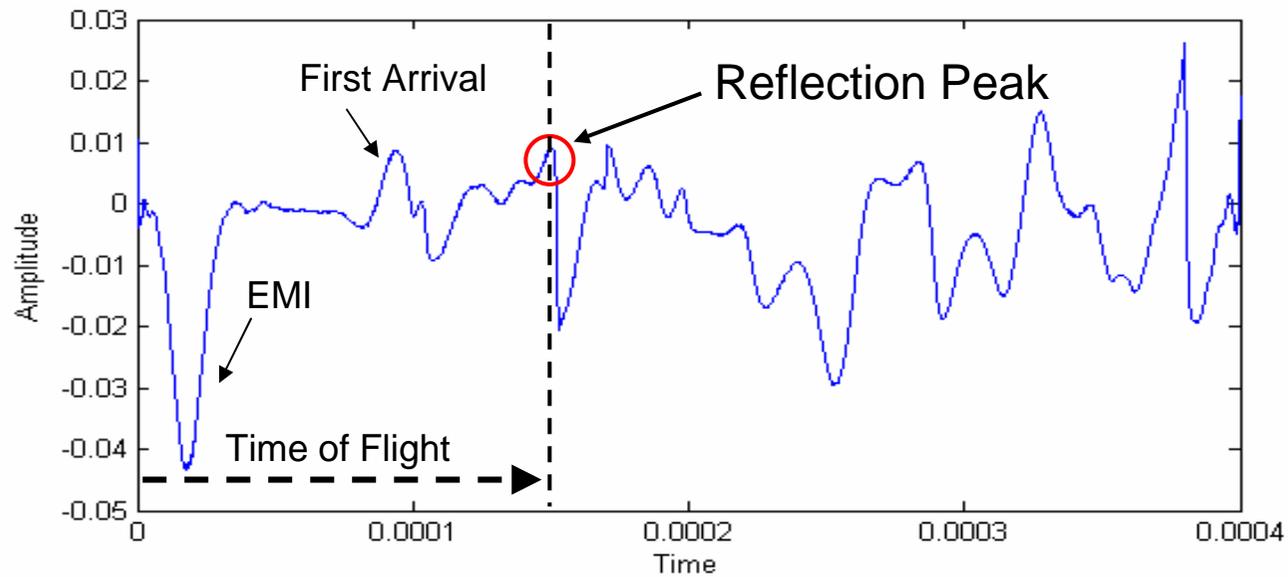

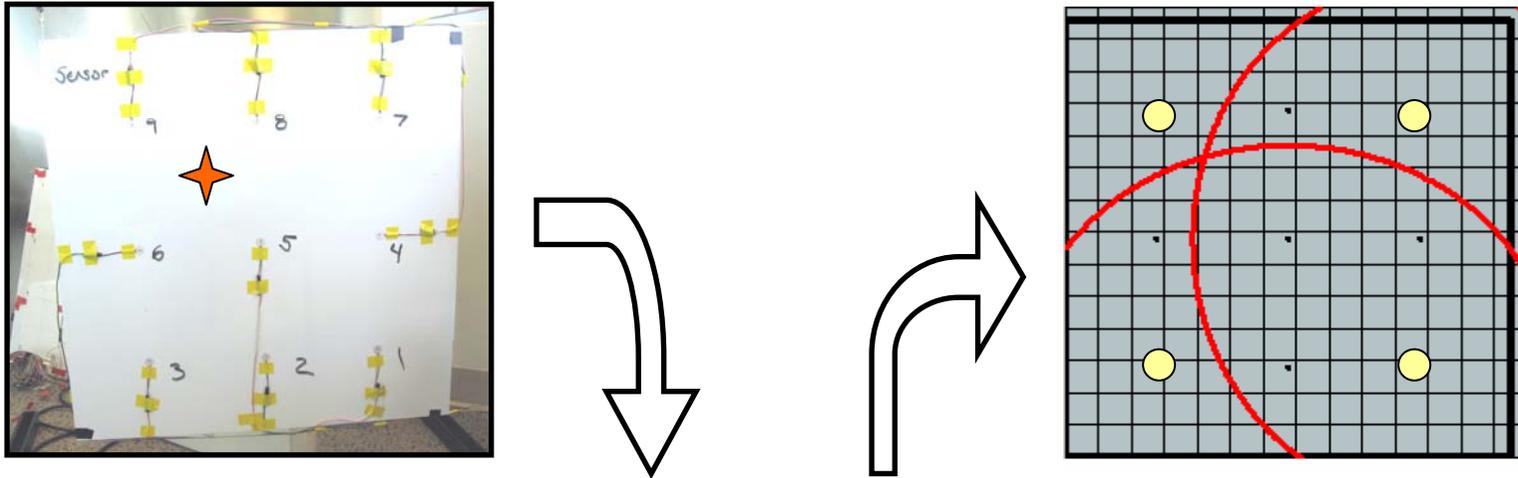

Wavelet Transform

PSD Cross Correlation

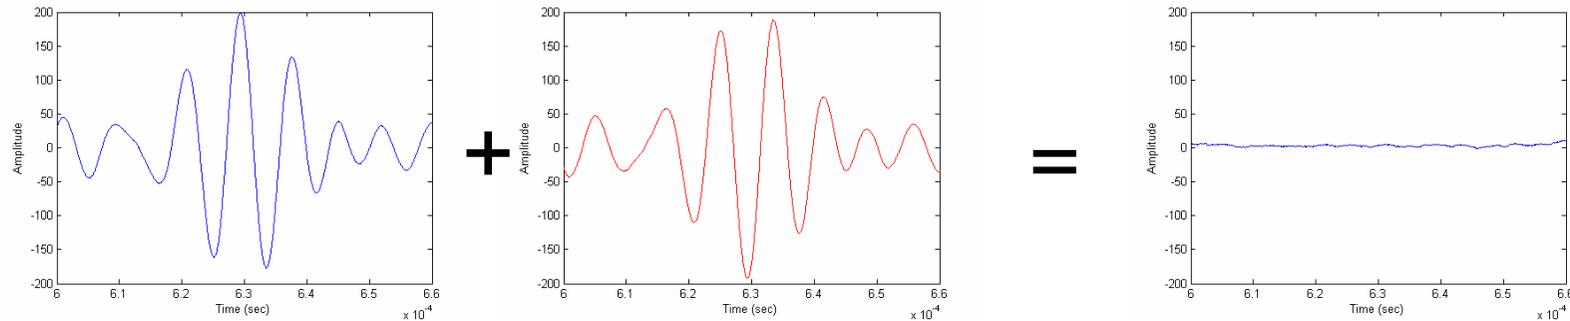

Wave Reflection Triangulation Results

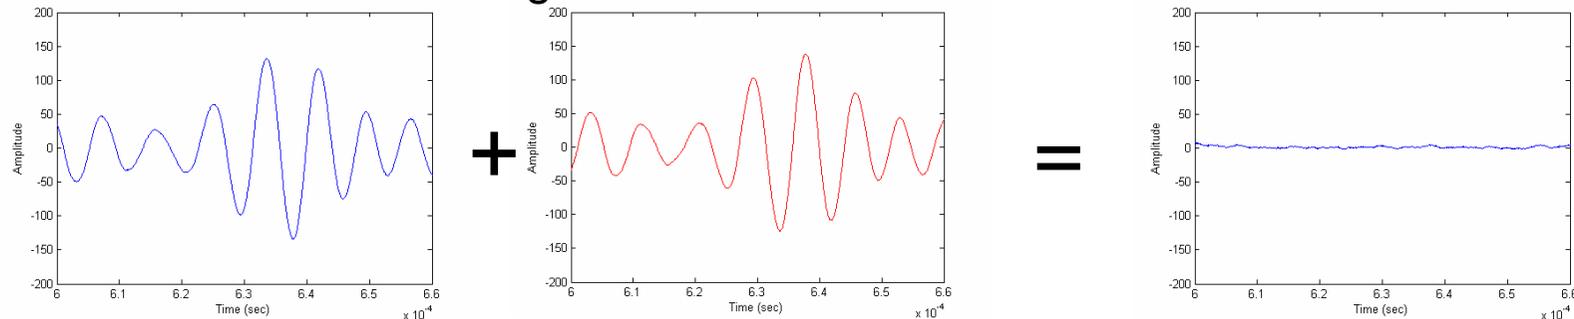

Time Reversal methods were unable to detect damage due to linearity of damage

Undamaged

Damaged

Time reversal methods with baseline measurements have the potential for increased sensitivity at the expense of acquisition time

The various analysis techniques compliment each other when combined as one tool

Data Acquisition Settings

Wavelet PSD

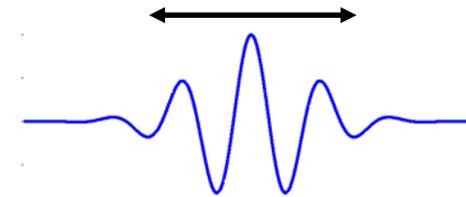

The screenshot displays the HOPS software interface with the following components:

- Left Panel (Data Acquisition Settings):**
 - H.O.P.S. Set Geometry
 - Set DAQ Filename: .EricDanAndy\HOPSet\DAQ\Thick_722.d
 - Sampling Rate (MHz): 25
 - Data Points \ Measurement: 10000
 - Pretrigger Points: 100
 - Averages: 50
 - Actuator Voltage Range: 1
 - Sensor Voltage Range: 1
 - Actuator Signal Amplitude: 10
 - Center Frequency: 250000
 - Burst Type: 10 Peak Windowed Sine, 5 Peak Windowed Sine, Morlet Wavelet (selected), Custom
 - Buttons: Set DAQ Settings, Save Settings, Load Settings
 - Copy Data dropdown
- Wavelet Section:**
 - Two plots showing wavelet analysis results with red 'X' marks.
 - Threshold: .03
 - Buttons: New DI, Wavelet, Baseline, Test, View DI, View Set
- PSD Section:**
 - Two plots showing Power Spectral Density analysis results with red shaded areas.
 - Threshold: 0.006
 - Buttons: New DI, PSD, Baseline, Test, View DI, View Set
- Triangulation Section:**
 - Plot showing triangulation analysis with red curved lines.
 - Threshold: 0.01
 - Buttons: Triangulation, View Set, Baseline, Test
- Time Reversal Section:**
 - Plot showing time reversal analysis with a red question mark.
 - Threshold: 0.01
 - Buttons: T Reversal, View Set, Baseline, Test

Triangulation Time Reversal

Future Work

More thorough investigation of optimal Lamb wave frequency

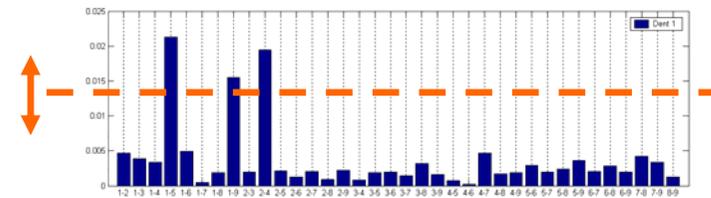

Further investigation into time-reversal methods

Determining and compensating for environmental factors

Incorporation of statistical analysis for determining proper damage threshold levels
